1. Purpose and Scope

The purpose of this document is to provide empirical norms for interpreting scores on the Threat Sensitivity Scale (TSS). The TSS is a five-item measure scored from 1 to 7, with the composite calculated as the mean of the five items. Possible composite scores therefore range from 1.0 to 7.0 in increments of .20. The norms reported here translate these raw scores into percentile ranks, allowing a given TSS score to be interpreted relative to the larger reference sample and, when supported by the available data, relative to more demographically specific reference groups.

The TSS was developed by March, Hasty, and Olivett (2024) as a brief self-report measure of dispositional sensitivity to the possibility of physical harm.[1] The current normative framework is intentionally hierarchical. Each raw TSS score can be located within the overall reference distribution, within a race-specific reference distribution, and, when sufficient data are available, within a race- and age-specific reference distribution. These levels provide complementary information rather than mutually exclusive alternatives. For example, an individual score may be relatively high compared with the full reference sample while being more typical among respondents of the same race and age. Demographic characteristics were incorporated into the norming framework only when the available evidence indicated that they meaningfully affected interpretation of the score; accordingly, the present norms incorporate race and age but do not stratify by gender.

These norms are based on a growing database assembled across multiple studies. The procedures used to construct the norms are designed to remain stable as additional observations are added, while the resulting percentile estimates and the range of ages supporting more specific norms will update as the reference sample grows. This document therefore describes both the current normative estimates and the rules used to generate them, with the full lookup tables provided to support transparent and reproducible interpretation of TSS scores.

---

[1]Scale development began with 19 candidate items describing ostensibly innocuous objects or situations and used iterative factor analysis to identify a five-item, single-factor measure. The resulting structure was replicated in an independent sample and demonstrated good internal reliability. Subsequent validation studies showed that TSS scores related in theoretically meaningful ways to relevant individual differences, the projection of physical threat onto ambiguous human targets, and behavioral responses during exposure to physical threat. The scale was designed to provide an easily administered measure of individual differences in physical threat sensitivity rather than a measure of general negativity, anxiety, or beliefs about a dangerous social world.

2. Norming Sample

The current normative database contains 7,271 participants drawn from seven contributing study samples. Sample sizes ranged from 499 to 2,008 participants, with no single study accounting for more than 28% of the combined database. All participants included in the normative sample had a valid TSS composite score. Item-level TSS responses were available for a subset of the combined database, reflecting differences in the variables retained across contributing datasets; consequently, inclusion in the normative sample was based on availability of the composite TSS score rather than item-level data.

Table 1
Composition of the Current TSS Normative Sample

Characteristic	Group	N	%
Study	1	1,002	13.78
	2	2,008	27.62
	3	499	6.86
	4	763	10.49
	5	499	6.86
	6	1,999	27.49
	7	503	6.92
Gender	Women	3,550	48.82
	Men	3,618	49.76
	Nonbinary	73	1.00
	Other	30	0.41
Race	White	5,220	71.79
	Black	960	13.20
	Hispanic	455	6.26
	Asian	387	5.32
	Native American	61	0.84
	Other	188	2.59

The normative sample spans much of adulthood. Age was available for 7,255 participants and ranged from 18 to 95 years (*M* = 45.63, *SD* = 15.86, *Mdn* = 44; interquartile range = 32–59). The sample was approximately evenly divided between women (48.82%) and men (49.76%), with 1.00% identifying as nonbinary and 0.41% reporting another gender. Racially, the sample included 5,220 White participants (71.79%), 960 Black participants (13.20%), 455 Hispanic participants (6.26%), 387 Asian participants (5.32%), 188 participants reporting another race (2.59%), and 61 Native American participants (0.84%).

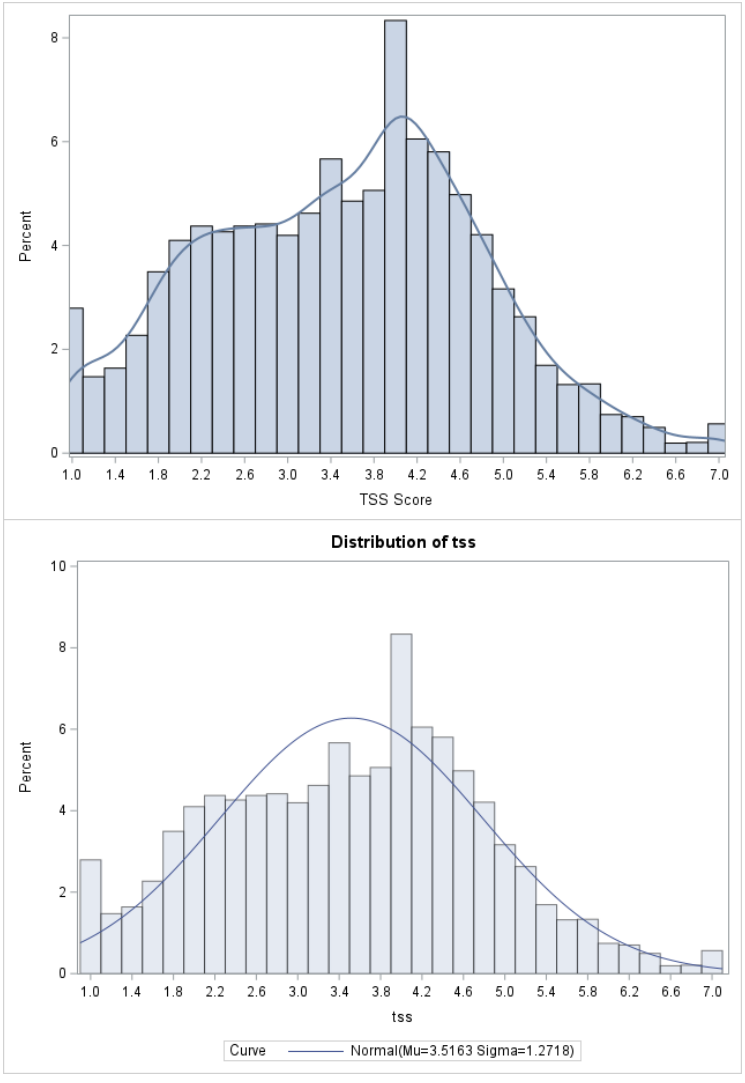

Race-specific norms are currently estimated for the four racial groups with the largest available reference samples: White, Black, Hispanic, and Asian respondents. Participants identifying as Native American or another race remain part of the overall normative reference sample, but the current group-specific sample sizes are insufficient to support separate race-specific norms. Similarly, all gender groups contribute to the overall reference distribution, although the analyses described below indicated that gender differences were not sufficiently large to warrant separate normative distributions. Age-specific norms are generated only when the available same-race reference sample satisfies the minimum sample-size and locality criteria described in Section 5.

3. TSS Measurement Characteristics

Before constructing normative reference distributions, we examined the overall score distribution, internal consistency, and variability across contributing studies. These analyses were intended to establish whether the TSS behaved consistently enough across samples to support a pooled normative database.

3.1 Overall Score Distribution

TSS scores were broadly distributed across the full possible range from 1.0 to 7.0. In the combined normative sample, the mean TSS score was 3.52 (*SD* = 1.27), with a median of 3.60 and an interquartile range of 2.60 to 4.40. The distribution was approximately symmetric (skew = 0.05) and somewhat flatter than a normal distribution (kurtosis = −0.48). Scores at the extreme ends of the scale were uncommon: 2.79% of respondents obtained the minimum possible score of 1.0, and 0.56% obtained the maximum score of 7.0. The 5th and 95th percentiles were 1.40 and 5.60, respectively. Together, these characteristics indicate substantial variability across the scale with little evidence of problematic floor or ceiling effects.

3.2 Internal Consistency

Internal consistency was examined separately within each contributing study rather than only in the pooled sample. Cronbach's alpha ranged from approximately **.82 to .84** across the seven study samples, indicating good and highly consistent reliability across datasets. The narrow range of reliability estimates is particularly useful for the norming project

because it suggests that differences among study samples are unlikely to reflect substantial differences in the internal coherence of the TSS.

Table 2
Internal Consistency of the TSS Across Contributing Studies

Study	Cronbach's α
1	. 843
2	[no item level data]
3	.832
4	.827
5	.831
6	.824
7	.845

3.3 Variation Across Studies

Mean TSS scores varied somewhat across the seven contributing studies, ranging from approximately 3.10 to 3.75, while study-specific standard deviations were highly similar, ranging from approximately 1.22 to 1.29. To quantify the extent to which TSS scores clustered by study, we estimated an empty random-intercept model with study as the grouping variable. The estimated between-study variance was 0.046 and the within-study variance was 1.575, corresponding to an intraclass correlation of .029. Thus, only about 2.9% of the total variance in TSS scores was attributable to differences among contributing studies.

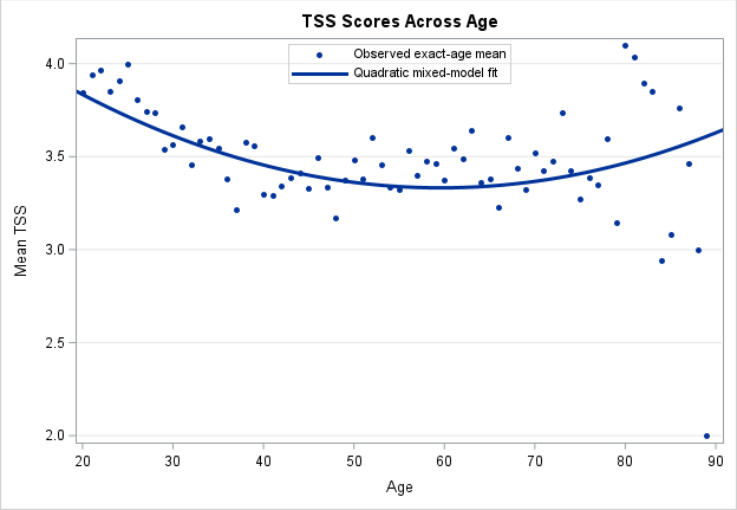

As a further sensitivity check, empirical percentile estimates calculated by weighting each study equally were nearly identical to those obtained when all participants were pooled directly. Differences were limited to a small number of lower-distribution percentile cutoffs and amounted to only one possible TSS score increment (.20). Given the small study-level variance, highly similar within-study reliability, and negligible effect of study weighting on the percentile estimates, the pooled participant-level sample was retained as the primary normative reference population.

4. Evaluation of Candidate Norming Variables

Demographic characteristics were evaluated as potential norming variables based on whether they produced differences in TSS scores large and consistent enough to change the practical interpretation of a raw score. Statistical significance alone was not treated as sufficient evidence for stratification, particularly given the size of the combined sample. Instead, the goal was to identify characteristics for which use of a more specific reference group provided meaningfully different information while retaining adequate reference-sample size.

4.1 Age

TSS scores varied systematically with age, and the association was nonlinear. In a mixed-effects model accounting for study-level clustering, both the linear and quadratic components of age were significant, and inclusion of the quadratic term improved model fit relative to a linear age model, $\chi^2(1) = 29.93$, $p < .001$. The resulting pattern was characterized by higher TSS scores among younger adults, declining scores through early and middle adulthood, followed by a modest leveling or rebound later in life.

In the figure to the right points represent observed mean TSS scores at each exact age. The fitted curve represents the quadratic fixed-effect trajectory from a mixed-effects model with a random intercept for contributing study. Note that exact-age means in the 80s and 90s are less precise because those ages have relatively few participants.

The same pattern was evident descriptively. Mean TSS scores were 3.82 among participants ages 18–29, 3.52 among those ages 30–39, 3.34 among those ages 40–49, 3.44 among those ages 50–59, 3.44 among those ages 60–69, and 3.50 among those ages 70 and older. Thus, the normative meaning of a given raw TSS score varies with age, particularly when comparing younger adults with middle-aged and older respondents.

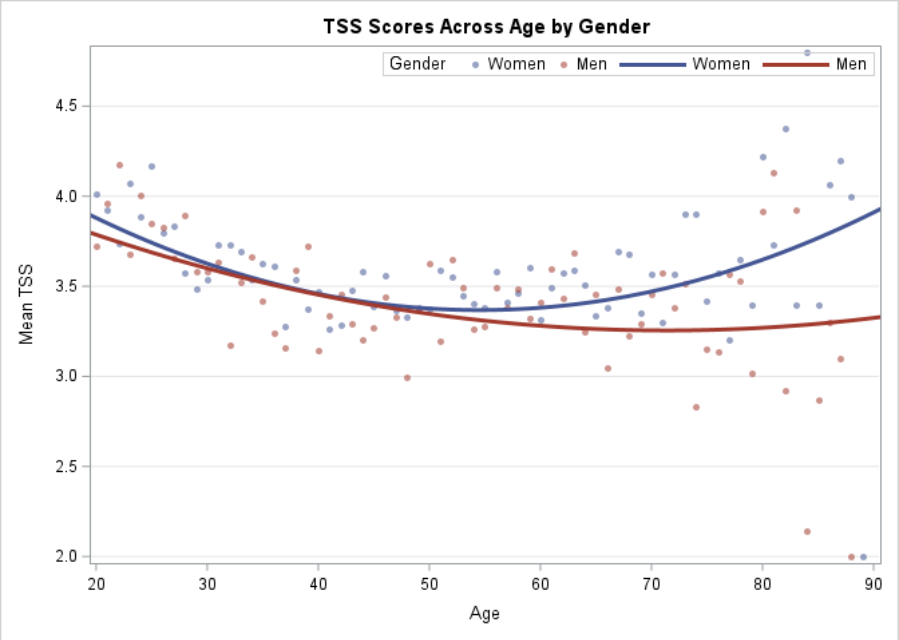

Because age is continuous and its relationship with TSS is nonlinear, fixed age bands were not used to construct the final norms. Instead, age was incorporated through an adaptive

local-reference procedure described in Section 5. This approach preserves age specificity while avoiding arbitrary category boundaries.

4.2 Gender

Women scored slightly higher on the TSS than men in the pooled sample, with raw means of 3.57 and 3.47, respectively. After accounting for study and the nonlinear association with age, the adjusted gender difference was approximately .07 TSS points and remained statistically significant, $p = .016$. Relative to the overall TSS standard deviation of approximately 1.27, however, this difference was very small.

We also examined whether the association between age and TSS differed by gender. A continuous age model provided some evidence of gender-related variation in the age trajectory, although these differences were small and were not reproduced as a reliable omnibus interaction when age was represented using broader age groups, $F(5,7144) = 1.26$, $p = .277$. A larger difference was observed among participants age 70 and older, but this isolated subgroup difference did not provide sufficient evidence for a general gender-specific norming structure. This decision will be re-examined as the sample grows.

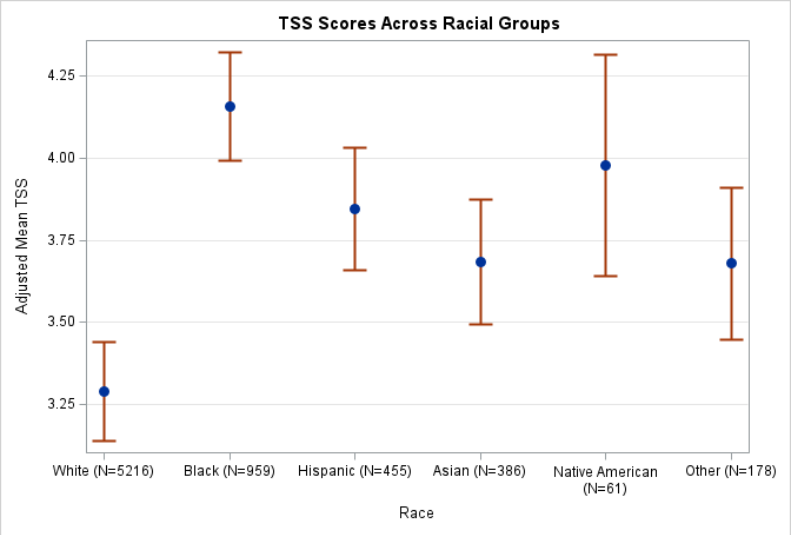

Accordingly, gender is retained as a descriptive characteristic of the reference sample but is not currently used to define separate normative distributions. Stratifying by gender would substantially reduce the size of race- and age-specific reference groups while providing relatively little change in percentile interpretation. This decision will be continuously reevaluated as the normative database grows.

4.3 Race

Race was associated with substantially larger differences in TSS scores. Raw mean scores were 3.32 among White respondents, 4.20 among Black respondents, 4.05 among Hispanic respondents, 3.70 among Asian respondents, 4.11 among Native American

respondents, and 3.74 among respondents reporting another race. These differences remained pronounced after accounting for age and study, with a significant overall race effect, $F(5,7241) = 95.69$, $p < .001$.

The practical consequences of these differences were large enough to alter the interpretation of the same raw TSS score. For example, a TSS score of 4.4 corresponds to approximately the 75th percentile in the overall reference sample, but approximately the 81st percentile among White respondents, 53rd percentile among Black respondents, 58th percentile among Hispanic respondents, and 73rd percentile among Asian respondents. Thus, race-specific reference distributions provide substantially different information from the overall distribution for some groups.

In the figure to the right, the points represent estimated mean TSS scores after accounting for the linear and quadratic association with age and study-level clustering. Error bars represent 95% confidence intervals.

The association between race and TSS also varied with age. Models including race-by-age terms provided evidence that the age trajectory was not identical across racial groups. This supported retaining both race and age in the most specific level of the normative framework rather than treating their contributions as interchangeable. Race-specific norms are currently reported for White, Black, Hispanic, and Asian respondents because these groups have sufficiently large reference samples. Native American respondents and respondents classified as another race remain included in the overall reference sample, but their current group-specific sample sizes are too small to support separate norms.

4.4 Norming Decisions

Taken together, these analyses supported inclusion of race and age, but not gender, in the current normative framework. Age showed a meaningful nonlinear association with TSS, while race produced substantial differences in both mean scores and percentile interpretation. Gender differences were detectable but small and did not justify the loss of

precision that would result from further subdividing race- and age-specific reference samples.

Table 3
Evaluation of Candidate Norming Variables

Variable	Evidence of TSS differences	Practical magnitude	Included in norms
Age	Yes, nonlinear	Meaningful	Yes
Gender	Small overall difference	Very small	No
Race	Large overall differences	Substantial	Yes
Race × *Age*	Age patterns differ across race	Relevant to local norms	Yes

5. Construction of the Normative Scores

Normative scores were constructed directly from the empirical TSS distributions rather than by assuming that TSS scores follow a normal distribution. Because the TSS composite can take only 31 possible values, from 1.0 to 7.0 in increments of .20, each possible raw score was assigned a percentile rank within the relevant reference sample. The same percentile procedure was used at each level of the normative hierarchy.

5.1 Empirical Percentile Calculation

Percentile ranks were calculated using a midrank approach that accounts for tied scores. For a given raw TSS score, the percentile rank equals the percentage of respondents scoring below that value plus one-half of the percentage obtaining the same score:

$$Percentile\ Rank = 100 \times \frac{N_{below} + \frac{1}{2}N_{equal}}{N}$$

This approach was employed because many respondents necessarily share the same composite score. It also avoids imposing a continuous or normally distributed model on a discrete empirical score distribution. Percentile ranks therefore reflect the observed reference sample directly.

5.2 Overall Norms

Overall norms were calculated using the complete normative reference sample. Each of the 31 possible TSS scores was assigned a percentile rank based on its location within the full distribution of valid TSS composite scores. These norms provide the broadest interpretation of a score and answer the question of where a respondent falls relative to the entire normative database.

Overall norms are available for all valid TSS scores regardless of the respondent's demographic characteristics.

5.3 Race-Specific Norms

Race-specific percentile ranks were calculated separately for White, Black, Hispanic, and Asian respondents using the same empirical midrank procedure. For each group, all respondents of that race with a valid TSS composite score contributed to the reference distribution.

Race-specific norms answer a different question from the overall norms: where a given raw score falls relative to others in the same racial group. Because the racial groups differed

meaningfully in their TSS distributions, the percentile associated with the same raw score can vary substantially across groups.

Participants identifying as Native American or another race remain included in the overall reference sample but are not currently assigned separate race-specific norms because the available group-specific reference samples are too small.

5.4 Race- and Age-Specific Norms

Age-specific norms were constructed within race using an adaptive local-reference procedure rather than fixed age bands. For each target age, the procedure begins with respondents of the same race at that exact age and expands outward symmetrically in one-year increments until the local reference sample contains at least 100 respondents.

The smallest qualifying age window is used. To preserve the meaning of an age-specific comparison, the window is not permitted to extend beyond ±10 years from the target age. Thus, a race- and age-specific norm is reported only when at least 100 same-race respondents can be identified within a maximum 20-year span centered on the target age.

For each supported target age, the empirical percentile distribution is then calculated from that local same-race reference sample using the same midrank procedure described above. The resulting norm therefore reflects both race and local age while remaining entirely empirical.

The adaptive procedure (1) avoids arbitrary boundaries, (2) allows narrower reference windows where data are dense, and (3) automatically improves as the normative database grows. As additional observations accumulate, previously unsupported ages may become eligible for race- and age-specific norms, and existing age windows may become narrower while the underlying norming rule remains unchanged.

5.5 Norm Availability and Hierarchy of Interpretation

The normative framework provides up to three complementary percentile ranks for a given TSS score:

1. **Overall percentile**, based on the full normative sample.
2. **Race-specific percentile**, based on the full same-race reference sample.
3. **Race- and age-specific percentile**, based on the local same-race age reference sample when the minimum-N (i.e., 100) and locality criteria are satisfied.

The more specific norms do not replace the broader norms. Instead, each provides a different frame of reference. A respondent may therefore be relatively high compared with

the full sample while being more typical within their racial group or among same-race respondents of a similar age.

When the race- and age-specific criteria cannot be satisfied, the overall and race-specific percentile ranks remain available, while the race- and age-specific percentile is left unreported. For transparency, the norming database also retains the local reference-sample size, age radius used, and observed minimum and maximum ages contributing to each race- and age-specific estimate.

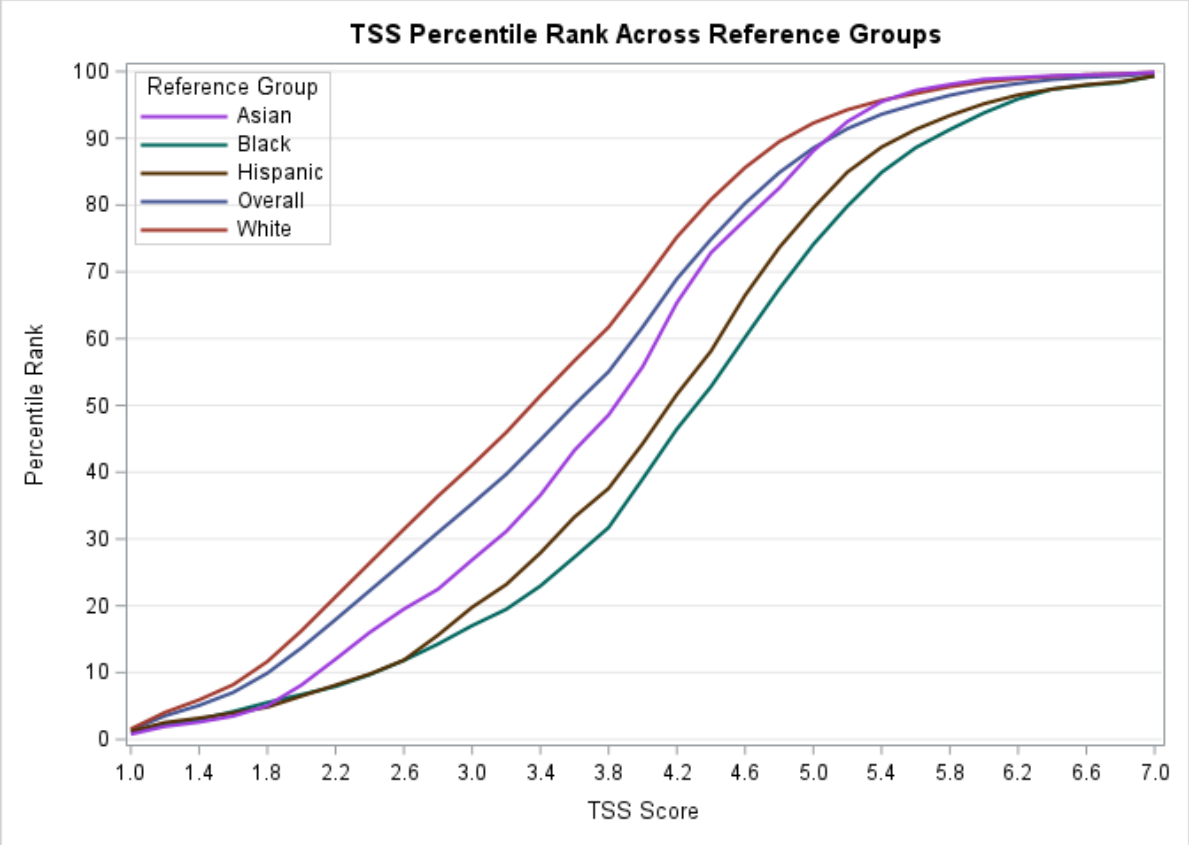

6. Interpretation and Use

The TSS norms are intended to provide descriptive context for an individual raw score. Percentile ranks indicate the respondent's relative position within a specified reference distribution. For example, a percentile rank of 75 indicates that the score falls above approximately 75% of the relevant reference distribution, with ties handled using the midrank procedure described above. Percentiles should not be interpreted as probabilities, diagnostic thresholds, or evidence that a particular score is inherently high or low outside the reference population being used.

6.1 Choosing a Reference Distribution

The three normative levels answer related but distinct questions. The **overall percentile** describes the respondent's standing relative to the complete normative sample. The **race-specific percentile** describes standing relative to respondents of the same race. When available, the **race- and age-specific percentile** further narrows the comparison to same-race respondents near the respondent's age.

The figure below displays the percentile rank associated with each raw TSS score across normative reference groups. Lines show the empirical percentile rank of each possible TSS score in the overall, White, Black, Hispanic, and Asian reference distributions.

No single percentile necessarily supersedes the others. The broader norms provide useful population-level context, whereas the more specific norms indicate how unusual the same score is within a more comparable reference group. For this reason, the normative tables retain all available levels rather than reporting only the most specific percentile.

Consider a 40-year-old Black respondent with a TSS score of 4.4. In the current normative database, that score corresponds to approximately the 75th percentile overall, the 53rd percentile among Black respondents, and the 63rd percentile among Black respondents near age 40.

These values describe the same raw score from three perspectives. Relative to the full normative sample, 4.4 is comparatively elevated. Within the Black reference distribution, however, the same score is close to the middle of the distribution. Restricting the comparison further to Black respondents of similar age places it somewhat above the midpoint. The difference among these percentiles is precisely why the norms preserve multiple reference frames.

6.2 When an Age-Specific Norm Is Unavailable

Race- and age-specific percentiles are reported only when at least 100 same-race respondents are available within ±10 years of the target age. Failure to meet this criterion does not prevent interpretation of the TSS score. The overall percentile and, when available, the race-specific percentile should still be reported. The absence of an age-specific percentile simply indicates that the current normative database does not yet support that more localized comparison.

The lookup tables additionally report the age radius, observed age range, and reference-sample size used for each race- and age-specific norm. These values allow users to evaluate the precision and locality of a particular reference distribution rather than treating all age-specific percentile estimates as based on identical samples.

6.3 Recommended Reporting

For most uses, we recommend reporting the raw TSS score together with all normative percentiles available for that respondent. A concise report might therefore take the form:

TSS = 4.4; overall percentile = 74.9, race-specific percentile = 52.8, race- and age-specific percentile = 62.6.

When interpretation centers on a particular comparison group, the corresponding percentile can be emphasized, but the reference group should always be stated explicitly. Terms such as “high TSS” or “low TSS” should likewise be tied to the relevant normative distribution rather than treated as absolute classifications.

7. Core Normative Tables

The following tables provide the primary reference values for interpreting TSS scores.

7.1 Overall and Race-Specific TSS Percentile

Table 4 presents percentile ranks for each possible raw TSS score in the overall reference sample and within the four racial groups for which separate norms are currently supported. Because these distributions differ meaningfully across groups, the table allows the same raw score to be interpreted against both a broad population reference and a more specific racial reference.

Table 4
Overall and Race-Specific TSS Percentile Norms

TSS	Overall	White	Black	Hispanic	Asian
1.0	1.4	1.6	1.0	1.2	0.8
1.2	3.5	4.0	2.2	2.5	1.9
1.4	5.1	5.9	3.0	3.2	2.6
1.6	7.0	8.2	4.2	4.0	3.5
1.8	9.9	11.7	5.5	4.8	5.0
2.0	13.7	16.3	6.7	6.5	8.1
2.2	17.9	21.4	7.9	8.1	12.0
2.4	22.3	26.4	9.7	9.8	16.0
2.6	26.6	31.5	11.8	11.9	19.5
2.8	31.0	36.4	14.3	15.6	22.5
3.0	35.3	41.1	17.0	19.8	26.9
3.2	39.7	46.0	19.5	23.2	31.1
3.4	44.8	51.4	23.0	27.9	36.6
3.6	50.1	56.7	27.3	33.3	43.3
3.8	55.1	61.7	31.7	37.6	48.6
4.0	61.8	68.3	39.0	44.3	55.8
4.2	68.9	75.2	46.5	51.6	65.4
4.4	74.9	80.8	52.8	58.1	72.9
4.6	80.3	85.6	60.2	66.5	77.8
4.8	84.9	89.5	67.4	73.6	82.6
5.0	88.5	92.3	74.1	79.6	88.1
5.2	91.4	94.3	79.8	84.9	92.5

5.4	93.6	95.7	84.9	88.7	95.5
5.6	95.1	96.7	88.6	91.3	97.2
5.8	96.4	97.7	91.3	93.4	98.1
6.0	97.5	98.4	93.8	95.2	98.8
6.2	98.2	98.9	95.9	96.5	99.1
6.4	98.8	99.3	97.3	97.4	99.4
6.6	99.1	99.5	97.9	98.0	99.5
6.8	99.3	99.6	98.3	98.5	99.6
7.0	99.7	99.8	99.3	99.3	99.9

Note. Values are empirical midrank percentile ranks. Race-specific norms are based on the full available same-race reference sample. Current reference-group sizes are 5,220 White, 960 Black, 455 Hispanic, and 387 Asian respondents.

7.2 Current Availability of Race- and Age-Specific Norms

Table 5 summarizes the ages for which the current database supports race- and age-specific norms. These ranges reflect the present size and age distribution of each racial reference sample and should therefore be viewed as version-specific rather than fixed properties of the scale. As the normative database grows, supported age ranges may expand and the local age windows used to generate the estimates may become narrower.

Table 5
Current Availability of Race- and Age-Specific Norms

Race	First Supported Age	Last Supported Age	Number of Supported Ages	Gaps Within Range
Asian	18	55	38	No
Black	18	73	56	No
Hispanic	18	65	48	No
White	18	88	71	No

Note. Availability is based on the current normative database and will change as additional observations are added. A race- and age-specific norm is available when at least 100 same-race respondents can be obtained within a maximum radius of ±10 years from the target age.

7.3 Summary of the TSS Normative Reference Levels

Table 6 summarizes the three normative reference levels used throughout this document. The overall and race-specific norms use the full available reference sample at their respective levels, whereas race- and age-specific norms use the smallest same-race age window that contains at least 100 respondents, up to a maximum radius of ±10 years.

Table 6
Summary of the TSS Normative Reference Levels

Norm Level	Reference Sample	Minimum N	Age Criterion
Overall	Entire normative sample	—	None
Race	Entire same-race sample	—	None
Race + age	Local same-race sample	100	Smallest qualifying window, maximum ±10 years

The complete race × age × TSS lookup is provided in *Appendix A*. That appendix contains the full set of available percentile estimates and the reference-sample information underlying each age-specific norm, allowing users to move from the compact tables presented here to the exact normative values for a particular race, age, and TSS score.

8. Versioning and Future Updates

These norms reflect the current TSS normative database, versioned by release date and total reference-sample size. The present version is based on N = 7,271 participants. The core norming rules described in this document will remain fixed across updates unless a methodological review indicates that revision is warranted.

As additional data are added, overall and subgroup reference Ns will increase, percentile estimates may shift slightly, and the range of ages supporting race- and age-specific norms may expand. Earlier versions should therefore remain archived and identifiable so that normative interpretations can be tied to the specific reference database used at the time.

Appendix A. The Full Threat Sensitivity Scale

The Threat Sensitivity Scale (TSS; March, Hasty, & Olivett, 2024) is a brief five-item measure of dispositional sensitivity to the possibility of physical harm. Respondents are asked to consider a set of otherwise relatively innocuous objects, people, and situations and indicate how likely they believe they would be to experience physical harm in each case. Responses are made on a 1–7 scale, anchored from 1 = Unlikely to 7 = Likely, with 4 = Neither likely nor unlikely. The five items are averaged to create the composite TSS score.

The final five items are:

1. An unlocked door
2. A stranger
3. Camping in the woods
4. An old wooden bridge
5. The edge of a mountain

The original scale-development paper provides the full administration instructions and validation of the five-item measure.

March, D. S., Hasty, C., & Olivett, V. (2024). *The threat sensitivity scale: A brief self-report measure of dispositional sensitivity toward perceiving threats to physical harm*. *Scientific Reports, 14*, 11304. https://doi.org/10.1038/s41598-024-61476-7

Appendix B. Full TSS Master Norming Lookup

The following table provides the complete normative lookup for every observed age, supported racial group, and possible TSS score in the current normative database. Each row retains the broader overall and race-specific norms regardless of whether a race- and age-specific norm is available. When the local age-reference criterion is not met, the race- and age-specific percentile and its associated reference-sample information are left blank.

Table headings are defined as follows:

Race: Racial reference group used for the race-specific and race-and-age-specific norms.

Age: Target age for the normative lookup.

TSS Score: Raw TSS composite score, ranging from 1.0 to 7.0 in increments of .20.

Overall Percentile: Empirical percentile rank relative to the complete normative sample.

Race Percentile: Empirical percentile rank relative to all respondents in the same racial reference group.

Race + Age Percentile: Empirical percentile rank relative to the local same-race age reference sample. Reported only when the age-specific norming criteria are satisfied.

Age Norm Available: Indicates whether a valid race- and age-specific norm is available for that race and target age (1 = available, 0 = unavailable).

Age Radius Used: Number of years above and below the target age required to obtain the local reference sample. The smallest qualifying radius is used, with a maximum of ±10 years.

Youngest Reference Age: Youngest observed age included in the race- and age-specific reference sample.

Oldest Reference Age: Oldest observed age included in the race- and age-specific reference sample.

Age-Specific Reference N: Number of same-race respondents included in the local age-specific reference sample. A minimum of 100 is required.

Same-Race N Within ±10 Years: Total number of same-race respondents available within ±10 years of the target age, regardless of whether a narrower qualifying window was used.

Note: Because the overall and race-specific percentiles do not depend on age, these values repeat across target ages; they are retained in the full lookup so that all available normative reference levels can be interpreted from a single row.
